School of Computing and Information Systems COMP90038 Algorithms and Complexity Tutorial Week 12

Sample answers

- 1. Recall the definition of the knapsack problem. Given a set of items $S = \{i_1, i_2, \dots i_n\}$ with
 - weights: $w(i_1), w(i_2), \dots, w(i_n)$ • values: $v(i_1), v(i_2), \dots, v(i_n)$

and a knapsack of capacity W, find the most valuable selection of items that will fit in the knapsack. That is, find a set $I \subseteq S$ such that $\sum_{i \in I} w(i) \leq W$ and so that $\sum_{i \in I} v(i)$ is maximised.

Define the *benefit* of an item i to be the rational number v(i)/w(i). Consider the following greedy approach to the problem:

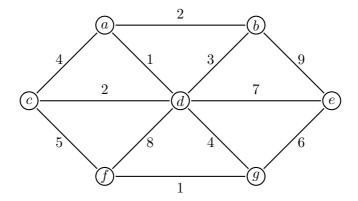

```
Let A[1]...A[n] hold the items from S, in decreasing order of benefit val \leftarrow 0 weight \leftarrow 0 k \leftarrow 1 while k \leq n \wedge weight + w(A[k]) \leq W do select A[k] val \leftarrow val + v(A[k]) weight \leftarrow weight + w(A[k]) k \leftarrow k + 1
```

That is, at each step, from the remaining items we simply pick the one that has the greatest benefit. Give a simple example to show that this greedy algorithm does not solve the knapsack problem.

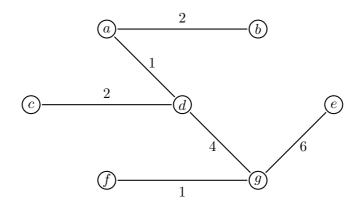

Answer: Assume capacity W=8 and take, for example, three items with (value, weight) pairs as follows: $i_1:(6,5), i_2:(4,4), i_3:(3,4)$.

The three are already in decreasing order of benefit. If we pick i_1 greedily (since it has the highest benefit), there is room for no other item, so the value we achieve is 6. Of course, the better solution is to pick i_2 and i_3 , for a total value of 7.

2. Work through Prim's algorithm for the graph below. Assume the algorithm starts by selecting node a. Which edges are selected for the minimum spanning tree, and in which order?

Answer: The first edge found is a-d. After that, a-b and c-d are added in either order. Last come d-g, g-f, and e-g. This gives the following minimum spanning tree, of cost 16:

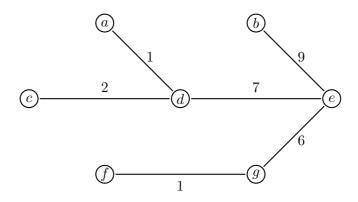

3. Use Dijkstra's algorithm to find the shortest paths for node e in the previous question's graph. That is, run the algorithm to determine the length of the shortest path from e to v, for all seven nodes v. Is the shortest path from e to b part of the graph's minimum spanning tree?

Answer: The shortest paths from e are found to be:

 $\begin{array}{cccc} a: & 8 \\ b: & 9 \\ c: & 9 \\ d: & 7 \\ e: & 0 \\ f: & 7 \\ g: & 6 \end{array}$

We already saw in the previous question that the e-b edge is not part of the graph's minimum spanning tree. These are the edges captured by the 'prev' relation:

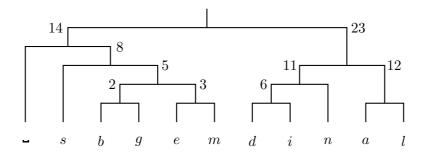

4. Lemuel Gulliver wishes to compress the string "all_big_endians_and_all_small_endians". Help him by building a Huffman tree for the string (there may be several valid trees) and assign a binary code accordingly, to each of the eleven characters involved (we have used _ to make each space character visible). The frequencies are:

a b d e g i l m n s <u>-</u> 6 1 3 2 1 3 6 1 5 3 6

How many bits are required for the encoded string?

Answer: Different trees are possible. Here is one:

Based on this Huffman tree, we assign codes as follows:

a	b	d	e	g	i	l	m	n	s	
110	01100	1000	01110	01101	1001	111	01111	101	010	00
